

Modelling and Robust Position/Force Control of a Piezoelectric Microgripper

Micky Rakotondrabe, Cédric Clévy and Philippe Lutz

Abstract—This paper deals with the control of a piezoelectric microgripper based on two piezocantilevers. To avoid the destruction of the manipulated micro-object and to permit a high accurate positioning, the microgripper is controlled on position and on force. Each piezocantilever is separately modelled and controlled: while the one is controlled on position, the second is controlled on force. Because the models are subjected to uncertainties and the micromanipulation requires good performances, a H_∞ robust controller is designed for each system. The experiments end the paper and show that good performances are obtained.

I. INTRODUCTION

In micromanipulation, i.e. manipulation of object from $1\mu m$ to $1mm$ sizes, the required accuracy is generally sub-micrometric. Instead of hinges, active materials are used to design systems for micromanipulation. In fact, hinges are characterized by frictions and may decrease the performances (accuracy) of the micromanipulation. Among these active materials, piezoelectric materials are widespread because of their fast response time and their high resolution. One of the main applications of piezoelectric materials in microsystems is piezoelectric microgrippers. A piezoelectric microgripper is based on two piezoelectric cantilevers (piezocantilevers). It is used to pick a micro-object, transport and place it with a high positioning accuracy. Nevertheless, to avoid the destruction of the micro-object, a control of the manipulation force is necessary.

In the litterature, many studies have been done on the modelling and control of a piezocantilever but few concern a whole microgripper. The majority of these studies especially refer to the deflection of the cantilever: [1] is an example in the linear approach while [2][3][4][5] takes into account the nonlinearities of the material. On the other hand, the control of the force is today a partially solved problematic because it requires the integration of a very small sensor, the use of the piezoelectric properties or a compliant structure. Up to now, very few solutions are proposed: [6][7][8].

In this paper, we propose to model and control a piezoelectric microgripper. In order to ensure good performances for the micromanipulation, a H_∞ robust con-

troller is used. The position (directly measured) and the manipulation force (estimated) are considered as the references. The paper is organized as follows. First, the modelling of the microgripper is presented. Then, the design of the H_∞ controller for each piezocantilever is presented. Finally, the experimental results are presented and discussed.

II. MODELLING

Let the Fig. 1 present the piezoelectric microgripper manipulating a micro-object. In this figure, F_m is the manipulation force applied by the two piezocantilevers to the micro-object. Our objective is to control the position of the micro-object by means of one piezocantilever and to maintain a constant value of F_m by means of the second piezocantilever. Because the adhesion forces [9] are insignificant relative to the manipulation force range of our concern (more than millinewton), and because we experiment objects from $500\mu m$ to $1.5mm$ in size, they will not be taken into account in this paper.

Fig. 1. A piezoelectric microgripper manipulating a micropart.

The relation between the applied voltage U_i , the force F_i applied to the piezocantilever at its tip and the resulting deflection δ_i , with $i \in \{l, r\}$, in the static mode is [10]:

$$\delta_i = d_i \cdot U_i + s_i \cdot F_i \quad (1)$$

where $d_i > 0$ is the equivalent piezoelectric constant of the piezocantilever and $s_i > 0$ is the equivalent elastic constant.

However, it has been shown that the transient part of the (U_i, δ_i) -transfer and the transient part of the (F_i, δ_i) -transfer of a piezocantilever are similar [11]. Thus, we have:

$$\delta_i = (d_i \cdot U_i + s_i \cdot F_i) \cdot D_i(s) \quad (2)$$

where $D_i(s)$ (such as $D_i(0) = 1$) represents the dynamic part and s the Laplace variable.

On the other hand, the relation between the manipulation force F_m and the contraction of the micro-object is:

$$(\delta_l - \delta_{l0}) - (\delta_r - \delta_{r0}) = s_o \cdot D_o(s) \cdot F_m \quad (3)$$

where $s_o > 0$ is the elastic constant of the micro-object, $D_o(s)$ (such as $D_o(0) = 1$) is its dynamic characteristic and δ_{l0} and δ_{r0} are the deflections of the left and right piezocantilevers before touching the object (Fig. 2).

Fig. 2. Initial situation: the micro-object is not in contact with the piezocantilevers.

Noting $\Delta\delta = \delta_{l0} - \delta_{r0}$ and replacing $F_l = F_r = -F_m$ in the (Eq. 2), we have:

$$\begin{cases} \delta_l = (d_l \cdot U_l - s_l \cdot F_m) \cdot D_l(s) \\ \delta_r = (d_r \cdot U_r - s_r \cdot F_m) \cdot D_r(s) \\ (\delta_l - \delta_r) - \Delta\delta = s_o \cdot D_o(s) \cdot F_m \end{cases} \quad (4)$$

Without loss of generality, we choose the left piezocantilever for the force F_m actuation while the right one for the micro-object position actuation. From the set of equations (Eq. 4), two approaches are possible to model the microgripper:

- the first approach uses one bivariable system where the inputs are the two voltages and the outputs are the deflection δ_r and the force F_m . It takes into account the effects of the piezocantilevers deflections to each other. So, it is possible to design a multivariable controller leading to very good performances. However, this approach needs a precise model,
- the second approach consists in modelling independently the two piezocantilevers. While the one is modelled on force, the second is modelled on deflection. The advantage is that the two models are easier than of the first approach. However, since the deflection of one cantilever disturbs that of the other, and vice versa, the design of each feedback controller should takes into account such disturbances.

In both approaches, the models are dependent on the characteristics of the micro-object. In this paper, we choose the second approach because of the simplicity of the models and of the issued controllers.

A. Model of the voltage/deflection transfer

Here, we model the right piezocantilever. From the second equation of the set (Eq. 4), we have the nominal model:

$$\delta_r = d_r \cdot D_r(s) \cdot (U_r + b_r) \quad (5)$$

where $b_r = -\frac{s_r \cdot F_m}{d_r}$ is an input disturbance to be rejected. Fig. 3 shows the corresponding scheme.

Fig. 3. Scheme of the nominal model of the right piezocantilever.

B. Model of the voltage/force transfer

The left piezocantilever is modelled in this part. From the first and last equations of the set (Eq. 4), we have:

$$F_m = \frac{1}{(s_o + s_l)} \cdot D_k(s) \cdot (d_l \cdot D_l(s) \cdot U_l - \delta_r - \Delta\delta) \quad (6)$$

with:

$$D_k(s) = \frac{(s_o + s_l)}{(D_o(s) + D_l(s))} \quad (7)$$

and $D_k(0) = 1$.

The (Eq. 6) clearly shows that the model depends on the characteristics of the micro-object. Nevertheless, it is not practical to identify the model and to synthesize a controller at each change of manipulated micro-object. Thus, we propose to have a nominal model independent of the micro-object characteristics, i.e. $s_o = 0$ and $D_k(s) = 1$, and use a robust controller to ensure the stability and the performances. Such hypothesis will be verified in the experimental results. Finally, we have the following nominal model:

$$F_m = \frac{d_l}{s_l} \cdot D_l(s) \cdot U_l + F_{pert} \quad (8)$$

where $F_{pert} = -\frac{(\delta_r + \Delta\delta)}{s_l}$ is an output disturbance to be rejected. Fig. 4 shows the corresponding scheme.

Fig. 4. Scheme of the nominal model of the left piezocantilever.

C. Identification

For our experiments, we use two unimorph piezocantilevers based on a *PIC151* piezolayer [12] and a Copper layer. The sizes of each piezocantilever are: $15\text{mm} \times 2\text{mm} \times 0.3\text{mm}$ (length, width and thickness) where the thickness of the piezolayer is 0.2mm . The experimental setup (Fig. 5) is made up of:

- the microgripper,
- two laser sensors (Keyence sensor with 500nm of accuracy) to measure the deflections of the piezocantilevers,
- an amplifier with two lines for U_l and U_r ,
- a computer-DSPACE material to acquire the measurements and to generate the input voltages U_l and U_r .

Fig. 5. Experimental setup.

For each piezocantilever, a harmonic experiment was performed. Afterwards, the (U_i, δ_i) -transfer function is identified in the frequency domain. A second order model is assumed to be sufficient for piezocantilevers [13]. We have:

$$\begin{cases} d_r = 0.545 \left[\frac{\mu\text{m}}{\text{V}} \right] \\ D_r(s) = \frac{1}{1.86 \times 10^{-8} \cdot s^2 + 4.1 \times 10^{-6} \cdot s + 1} \end{cases} \quad (9)$$

and

$$\begin{cases} d_l = 0.525 \left[\frac{\mu\text{m}}{\text{V}} \right] \\ D_l(s) = \frac{1}{1.85 \times 10^{-8} \cdot s^2 + 2.72 \times 10^{-6} \cdot s + 1} \end{cases} \quad (10)$$

Fig. 6 shows the results of (U_i, δ_i) -transfer function for the right piezocantilever.

Fig. 6. Magnitude of the right piezocantilever.

Finally, to identify the elastic constant s_i , a mass is hung on at the tip of each piezocantilever and the resulting deflection is measured. We have $s_r = s_l = 1.931 \times 10^{-3} \left[\frac{\text{m}}{\text{N}} \right]$.

Because the characteristics of the micro-object have been neglected in the nominal model, the latter is subjected to uncertainties. Such approach let us avoid the model identification and the controller synthesis of at each change of micro-object. Therefore, we choose a robust controller to ensure the stability and performances robustness face to the uncertainties, we use the H_∞ controllers. Moreover, the disturbance rejection will be taken into account during the controller design.

III. CONTROL OF THE DEFLECTION δ_r

Let the Fig. 7 be the closed-loop scheme. In the figure, δ_r^r indicates the reference input. Two weighting functions are used: W_1^T for the closed-loop performances and W_2^T for the disturbance rejection.

A. Standard form

Let $P_r(s)$ be the augmented system including the nominal system and the weighting functions. Fig. 8 shows the corresponding standard scheme.

The standard H_∞ problem consists in finding an optimal value $\gamma > 0$ and a controller $K_i(s)$ stabilizing the closed-loop scheme of the Fig. 8 and guaranteeing the following inequality [14]:

Fig. 7. The closed-loop scheme with the weighting functions.

Fig. 8. The standard form.

$$\|F_{low}(P_i(s), K_i(s))\|_\infty < \gamma \quad (11)$$

where $F_{low}(\cdot, \cdot)$ is the lower Linear Fractional Transformation and is defined here by $F_{low}(P_r(s), K_r(s)) = \frac{o_r(s)}{e_r(s)}$. From the Fig. 7, we have:

$$o_r = W_1^r \cdot S_r \cdot \delta_r^r - W_1^r \cdot S_r \cdot G_r \cdot W_2^r \cdot i_r \quad (12)$$

where $S_r = (1 + K_r \cdot G_r)^{-1}$ is the sensitivity function.

Using the condition (Ineq. 11) and the (Eq. 12), we infer:

$$\begin{aligned} \|W_1^r \cdot S_r\|_\infty < \gamma & \Leftrightarrow |S_r| < \frac{\gamma}{|W_1^r|} \\ \|W_1^r \cdot S_r \cdot G_r \cdot W_2^r\|_\infty < \gamma & \Leftrightarrow |S_r \cdot G_r| < \frac{\gamma}{|W_1^r \cdot W_2^r|} \end{aligned} \quad (13)$$

To solve the problem (Ineq. 13), we use the Glover-Doyle algorithm which is based on the Riccati equations [15][16]. The issued controller K_r is robust in the fact that it ensures the stability and the performances even if the nominal system G_r has an uncertainty relative to the real plant. The wanted performances are introduced through the weighting functions.

B. Choice of the weighting functions

The transfer functions $\frac{1}{W_1^r}$ and $\frac{1}{W_1^r \cdot W_2^r}$ are chosen from the specifications respectively on the tracking performances and on the disturbance rejection. Thus, the weighting functions W_1^r and W_2^r can be automatically deduced. The specifications are:

- the maximal response time is 100ms,
- the overshoot is null,
- the maximal statical error is 0.1%,
- finally, the rejection of the disturbance is a highpass filter with a cutting frequency more than 50Hz.

When the disturbance is a static force, its influence on the deflection has been chosen to be lower than $1.7 \left[\frac{\mu m}{10 m N} \right]$.

From the performances specifications, we choose:

$$\frac{1}{W_1^r} = 10^{-3} \cdot \frac{3 \cdot s + 1}{30 \times 10^{-3} \cdot s + 1} \quad (14)$$

Using the specifications on the disturbance rejection and using the equivalence $b_r = -\frac{s_r \cdot F_m}{d_r}$, we choose:

$$\frac{1}{W_1^r \cdot W_2^r} = 0.5 \times 10^{-7} \cdot \frac{3 \cdot s + 1}{3 \times 10^{-3} \cdot s + 1} \quad (15)$$

C. Calculation of the controller

The computed controller has an order of 5. To minimize the memory and time consumptions in the computer, the controller order has been reduced to 2 using the balanced realization technique [17]. We obtain:

$$\begin{cases} \gamma^{opt} = 10.1 \\ K_r = \frac{-15810 \cdot (s+4 \times 10^6) \cdot (s-1.4 \times 10^4)}{(s+1.5 \times 10^7) \cdot (s+0.3)} \end{cases} \quad (16)$$

IV. CONTROL OF THE FORCE F_m

Fig. 9 shows the closed-loop scheme. In the figure, F_m^r indicates the reference input. Two weighting functions are used: W_1^l for the closed-loop performances and W_2^l for the output disturbance rejection.

Fig. 9. The closed-loop scheme with the weighting functions.

From the Fig. 9, we have:

$$o_l = W_1^l \cdot S_l \cdot F_m^r - W_1^l \cdot S_l \cdot W_2^l \cdot i_l \quad (17)$$

where $S_l = (1 + K_l \cdot G_l)^{-1}$ is the sensitivity function.

Using the condition (Ineq. 11) and the (Eq. 17), we infer:

$$\begin{aligned} \|W_1^l \cdot S_l\|_\infty < \gamma & \Leftrightarrow |S_l| < \frac{\gamma}{|W_1^l|} \\ \|W_1^l \cdot S_l \cdot W_2^l\|_\infty < \gamma & \Leftrightarrow |S_l| < \frac{\gamma}{|W_1^l \cdot W_2^l|} \end{aligned} \quad (18)$$

A. Choice of the weighting functions

The following specifications are used:

- in order to maintain the micro-object during the positioning, the response time in force should be faster than the one of the deflection. For that, we choose a response time equal to $10ms$,
- the overshoot is null,
- the maximal static error is 1%,
- finally, the rejection of the disturbance is a highpass filter with a cutting frequency is $5Hz$. Such a value is chosen because the disturbance, which is the deflection of the other piezocantilever, has a low bandwidth (response time). When the disturbance is a static deflection, its influence on the output must be lower than $0.2 \left[\frac{mN}{40\mu m} \right]$.

From the performances specifications, we choose:

$$\frac{1}{W_1^r} = 10^{-2} \cdot \frac{3 \cdot s + 1}{3 \times 10^{-3} \cdot s + 1} \quad (19)$$

Using the specifications of the disturbance rejection and using the equivalence $F_{pert} = -\frac{(\delta_r + \Delta\delta)}{s_l}$, we choose:

$$\frac{1}{W_1^r \cdot W_2^r} = 10^{-2} \cdot \frac{3 \cdot s + 1}{30 \times 10^{-3} \cdot s + 1} \quad (20)$$

B. Calculation of the controller

The computed controller has an order of 5. Once again, the controller order has been reduced. We obtain:

$$\begin{cases} \gamma^{opt} = 1.02 \\ K_l = \frac{0.06 \cdot (s + 7.3 \times 10^8) \cdot (s^2 + 277 \cdot s + 8.2 \times 10^7)}{(s + 1.2 \times 10^6) \cdot (s + 1.9 \times 10^4) \cdot (s + 0.3)} \end{cases} \quad (21)$$

V. EXPERIMENTAL RESULTS

The two controllers given by the (Eq. 16) and the (Eq. 21) have been implemented to a computer-DSPACE real-time material. The Matlab-Simulink and the ControlDesk softwares were used for that. Since there is no adequate force sensor, a force estimator has been used [1]. Fig. 10 shows the principle scheme of the experiments.

Experiments with two types of micro-object were performed (Fig. 11): a flexible material (polystyrene) and a rigid material (rigid plastic). The sizes of the micro-objects were chosen so that $\Delta\delta \approx 0$. Its width, corresponding to the gap between the two piezocantilevers, is nearly $1mm$.

The results show that the same performances are obtained for both. Fig. 12 presents the experimental results with the rigid plastic mini gear. Initially, the deflection and the force are null. Then, a manipulation force reference of $5mN$ is applied. A small effect is seen on the deflection ($t = 1.3s$) but is quickly rejected. Between $t = 2s$ and $t = 5s$, a series of positive and negative steps (amplitude: $20\mu m$) in position reference is applied. As we can see, its influence on the force is also quickly rejected despite the high amplitude of the

Fig. 10. Principle scheme of the microgripper control.

Fig. 11. The microgripper manipulating a mini gear (in rigid plastic).

disturbance effect. Finally ($t = 5.8s$), the manipulation force reference is set to zero. Since the size of the micro-object is equal to the gap of the microgripper, a negative deflection reference should be applied to release it. On the other hand, we can remark that the accuracy is very high for the deflection and for the force. In fact, the static errors are very small and are not visible by the sensors.

In order to evaluate the response time, we zoom in the step reponse of each output (Fig. 13). It can be seen that the response time is exceeded: $t_{resp} \approx 250ms$ for the deflection and $t_{resp} \approx 150ms$ for the force. This is explained in the fact that the optimal value of γ is high for the deflection. For all that, the force response time still stays lower than the one of the deflection and the general performances are always suitable for the micromanipulation task requirements. In addition, ramp signals are often used as references in micromanipulation instead of step signals. So, such response times are largely sufficient.

VI. CONCLUSION

Piezoelectric materials are very prized in micromanipulation due to their rapidity and high resolution.

Fig. 12. Experimental results with a rigid plastic mini gear.

Fig. 13. Step response of each piezocantilever.

One of their application is piezoelectric microgrippers which are based on two piezocantilevers. A microgripper permits the pick-transport-and place of micro-objects with a high positioning accuracy. This paper has presented the modelling and the control of a piezoelectric microgripper dedicated to manipulate micro-objects. Both the positioning and the manipulation force were taken into account. For that, two separated models have been proposed: while one piezocantilever is modelled on deflection, i.e. position, the second is modelled on force. Because the characteristics of the manipulated micro-objects are neglected in the model, the nominal model is subjected to uncertainty. To ensure stability and performances, we have proposed a H_∞ controller for each

piezocantilever. Whatever the manipulated micro-object characteristics are, good performances suitable for the micromanipulation (disturbances rejection, micrometric positioning accuracy, submillinewton of force accuracy) were obtained in the experiments.
